*Abstract:* This paper estimates the size of the informal economy for the ECCU countries and 26 mainly Latin American countries in the early 2000s, being the first study to address this issue for the ECCU economies and many other Central American and Caribbean countries. Using a structural equation modeling approach it is found that a stringent tax system and regulatory environment, higher inflation and dominance of the agriculture sector are key factors in determining the informal economy. The results also confirm that higher degree of informality reduces labor unionization, the number of contributors to social security schemes and enrollment rates in education.

## I. INTRODUCTION

The measurement of the size of the informal economy has evoked considerable interest in both academic environments and policy circles, especially given its importance for emerging markets and developing countries. At the same time, measuring the informal economy is not an easy task. The biggest challenge arises from the lack of a clear definition of the informal economy. A wide range of similar terms are used in the literature such as hidden economy, shadow economy, clandestine economy, parallel economy, subterranean economy, unreported economy, cash economy and black economy. However, as a result of recent comprehensive publications and handbooks, there seems to exist some level of consensus regarding some terms. Following Feige (2005):

- The *illegal economy* consists of the income produced by those economic activities pursued in violation of legal statutes defining the scope of legitimate forms of commerce.
- The *unreported economy* consists of those legal and illegal economic activities that evade fiscal rules as codified in the tax laws.
- The *informal economy* comprises those economic activities that circumvent the costs and are excluded from the benefits and rights incorporated in the laws and administrative rules covering property relationships, commercial licensing, labor contracts, torts, financial credit and social systems. A summary measure of the informal economy is the income generated by economic agents who operate informally. Similarly, Portes et al. (1989) defines the informal economy as “a process

of income-generation characterized by one central feature: it is unregulated by the institutions of society, in a legal and social environment in which similar activities are regulated”.

Measuring the size of the informal economy is important for many reasons. First, there seems to be strong evidence that suggests a direct and clear link between the size of the informal economy and tax evasion. Table 1 shows, by using data for the early 90s from Schneider and Enste (2000) and Silvani and Brondolo (1993), that there is a clear positive relationship between these two concepts. As extreme cases, countries like Bolivia, which had an informal economy share of approximately 65 percent, experienced VAT tax evasion of about 45 percent; while countries like New Zealand, which had a low share of informal activity, around 12 percent, had a much lower level of tax evasion, close to 5 percent. Second, the informal economy, as a job provider, has an impact on the viability of social security institutions, specifically in terms of the latter’s ability to provide protection while receiving enough financial support. For example, in the early 90s, while 94 percent of the labor force contributed to the social security system in Netherlands, this percentage was only 19 for Honduras<sup>2</sup>. Third, inaccurate perceptions about the actual size of the economy could seriously decrease the effectiveness of a wide variety of policies.

“early 2000s”, being the first study to address this issue for the Eastern Caribbean Currency Union (ECCU) economies and many other Central American and Caribbean countries. For this purpose, a structural equation model approach that considers the informal economy as a latent variable with multiple causes and indicators is used. This approach surpasses typical limitations of some commonly used time series methods because, among other reasons, it does not require information regarding the absolute value of the informal economy for *each* country at some point in time to pin down the evolution of the informal economy over time. On the contrary, this cross section approach needs this information for *only one country* in the sample. This method also allows the exclusive use of *real* variables, as opposed to *monetary* ones, which might underestimate and misrepresent the relevance of the informal economy in countries subject to high degree of dollarization in circulating currency.

We find that a stringent tax system and regulatory environment, higher inflation, dominance of the agriculture sector, and weakness in governance are the key factors underlying the informal economy. The evidence obtained also confirms that a higher degree of informality reduces labor unionization, the number of contributors to social security schemes and enrollment rates in intermediate education.

The size of the informal economy varies considerably from around 16 percent of total GDP for Bahamas to 70 percent for Paraguay. Notwithstanding, the average size of the informal economy for the ECCU and Caribbean countries (around 33 percent of GDP) is lower than for Latin American economies (average of 43 percent of GDP).

The relative contribution of each underlying factor to the overall size of the informal economy is also estimated for each country. For some countries like Antigua and Barbuda, Barbados and Trinidad and Tobago, the key element is tax burden. For example, for the period under consideration, Antigua and Barbuda had the highest marginal corporate and personal tax rates of 55 and 35 percent respectively. For others like St. Vincent and the Grenadines, St. Lucia and Belize, the importance of the agriculture sector appears to be decisive, with around 75 percent of exports concentrated in agriculture and food products. For other countries like Paraguay and the Dominican Republic, labor rigidities are some of the most important factors, with minimum wages representing 170 percent and 90 percent of the corresponding GDP per capita.

The paper is organized as follows. The next section reviews the different methods used by the literature to estimate the size of the informal economy. It also carefully explains the “Multiple Indicators, Multiple Causes” (MIMIC) approach, which is the econometric method used in this study. Section III presents the set of countries and variables used in the analysis. The empirical results are discussed in Section IV, and Section V contains some concluding remarks.

## **II. METHODS FOR MEASURING THE SIZE OF THE INFORMAL ECONOMY**

Many alternative methods have been used to measure the size of the informal economy<sup>3</sup>.

Some approaches use direct methods based on surveys, but most studies use indirect

---

<sup>3</sup> A thorough review of these approaches is discussed in Schneider and Enste (2000) and the OECD handbook “Measuring the Non-Observed Economy” released in 2002.

methods based on (i) the discrepancy between national expenditure and income statistics, (ii) the discrepancy between the official and actual labor force, (iii) the “electricity approach” of Kauffman and Kaliberda (1996), (iv) the monetary “transaction approach” of Feige (1979), (v) the “currency demand” approach of Cagan (1958) and others, and (vi) the “Multiple Indicators, Multiple Causes” (MIMIC) approach. A brief description of each methodology, as well as a detailed explanation of the MIMIC approach, is provided below.

***Surveys***<sup>4</sup>: These micro approaches use surveys and samples based on voluntary replies, or tax auditing and other compliance methods to measure the informal economy. While providing great detail about the structure of the informal economy, the results are sensitive to the way the questionnaire is formulated and the respondents’ willingness to cooperate. Therefore surveys are unlikely to capture all informal activities.

***Discrepancy between national expenditure and income statistics***<sup>5</sup>: If those working in the informal economy were be able hide their incomes for tax purposes but not their expenditure; the difference between national income and national expenditure estimates could be used to approximate the size of the informal economy. If all the components of the expenditure side were measured without error and were constructed so that they were statistically independent from income factors, then this approach would indeed yield a good estimate of the size of the informal economy. Unfortunately this gap also reflects

---

<sup>4</sup> See for example Isanchen and Strom (1985), Witte (1987), Mogensen et al. (1995), Ivan-Ungureanu and Pop (1996) and Feige (1996).

<sup>5</sup> See for example MacAfee (1980) and Yoo and Hyun (1998).

other types of omissions and errors and several expenditure estimates are based on income calculations; thus the reliability of this method is seriously arguable.

***Discrepancy between official and actual labor force***<sup>6</sup>: If the total labor force participation is assumed to be constant, a decline in official labor force participation can be interpreted as an increase in the importance of the informal economy. Since movements in the participation rate might have many other explanations, such as the position in the business cycle, difficulty in finding a job and education and retirement decisions, these estimates represent weak indicators of the size of the informal economy.

***Electricity approach***<sup>7</sup>: Kaufmann and Kaliberda (1996) endorse the idea that electricity consumption is the single best physical indicator of overall (official and unofficial) economic activity. Using some findings that the electricity-overall GDP elasticity is close to one<sup>8</sup>, these authors suggest using the difference between growth of electricity consumption and growth of official GDP as a proxy for the growth of the informal economy. This method is simple and appealing, but has many drawbacks, including: (i) not all informal economy activities require a considerable amount of electricity (e.g. personal services) or use other energy sources (like coal, gas, etc.), hence only part of the informal economy growth is captured and; (ii) the electricity-overall GDP elasticity might significantly vary across countries and over time.

<sup>7</sup> See for example Del Boca and Forte (1982), Portes (1996) and Johson et al. (1997).

<sup>8</sup> See Dobozi and Pohl (1995).

**Transaction approach<sup>9</sup>:** Using Fischer's quantity equation,  $Money \cdot Velocity = Prices \cdot Transactions$ , and assuming that there is a constant relationship between the money flows related to transactions and the total (official and unofficial) value added, i.e.  $Prices \cdot Transactions = k (official\ GDP + informal\ economy)$ , it is straightforward to obtain the following equation  $Money \cdot Velocity = k (official\ GDP + informal\ economy)$ . The stock of money and official GDP estimates are known and money velocity can be estimated. Thus, if the size of the informal economy as a ratio of the official economy is assumed to be known for a benchmark year, then the informal economy can be calculated for the rest of the sample. Although theoretically attractive, this method has several weaknesses; for instance: (i) the assumption of  $k$  constant over time seems quite arbitrary and (ii) other factors like the development of checks and credit cards could also affect the desired amount of cash holdings and thus velocity.

**Currency demand approach<sup>10</sup>:** Assuming that informal transactions take the form of cash payments, in order not to leave an observable trace for the authorities, an increase in the size of the informal economy will, consequently, increase the demand for currency. To isolate this resulting "excess" demand for currency, Tanzi (1980) suggests to use a time series approach in which currency demand is a function of conventional factors, such as the evolution of income, payment practices and interest rates, and factors causing people to work in the informal economy, like the direct and indirect tax burden, government regulation and the complexity of the tax system. The size and evolution of the informal economy can be calculated by following two steps. First, the difference

---

<sup>9</sup> See for example Feige (1979), Boeschoten and Fase (1984) and Langfeldt (1984).

<sup>10</sup> See for example Cagan (1958), Gutmann (1977), Tanzi (1980, 1983), Scheneider (1997) Johnson et al. (1998).

between the evolution of currency when government regulations and the direct and indirect tax burden are held at their lowest value and the development of currency with the current (higher) burden of taxation and government regulations is calculated. Secondly, assuming the same income velocity for currency used in the informal economy as for legal money in the official economy, the size of the informal economy can then be computed and compared to the official GDP. However there are several problems associated with this method and its assumptions: (i) this procedure may underestimate the size of the informal economy, because not all transactions take place using cash as means of exchange; (ii) at least in the United States, increases in currency demand deposits seem to occur mainly because of a slowdown in demand deposits rather than an increase in currency used in informal activities; (iii) it seems extremely arbitrary to assume equal velocity of money in both types of economies and; (iv) the assumption of no informal economy in a base year is open to criticism.

***Multiple Indicators, Multiple Causes (MIMIC) approach<sup>11</sup>***: All methods described above consider only one indicator or manifestation of the informal economy -e.g. electricity consumption, money or cash demand. However, there exist several manifestations or symptoms showing up simultaneously. The MIMIC approach explicitly considers several causes, as well as the multiple effects of the informal economy. The methodology makes use of the associations between the observable causes and the observable effects of an unobserved variable, in this case the informal economy, to estimate the unobserved factor itself. The model for one latent variable can be described as follows:

---

<sup>11</sup> See for example Giles (1999) and Loayza (1997).

$$y = \lambda IE + \varepsilon \quad (1)$$

$$IE = \gamma' x + \nu \quad (2)$$

where  $IE$  is the unobservable scalar latent variable (the size of the informal economy),  $y' = (y_1, \dots, y_p)$  is a vector of indicators for  $IE$ ,  $x' = (x_1, \dots, x_q)$  is a vector of causes of  $IE$ ,  $\lambda$  and  $\gamma$  are the  $(p \times 1)$  and  $(q \times 1)$  vectors of the parameters and  $\varepsilon$  and  $\nu$  are the  $(p \times 1)$  and scalar errors. In other words, equation (1) links the informal economy with its indicators or symptoms, while equation (2) associates the informal economy with its causes. Assuming that these errors are normally distributed and mutually uncorrelated with  $\text{var}(\nu) = \sigma_\nu^2$  and  $\text{cov}(\varepsilon) = \Theta_\varepsilon$ , the model can be solved for the reduced form as a function of observable variables by combining equations (1) and (2):

$$y = \pi x + \mu \quad (3)$$

where  $\pi = \lambda \gamma'$ ,  $\mu = \lambda \nu + \varepsilon$  and  $\text{cov}(\mu) = \lambda \lambda' \sigma_\nu^2 + \Theta_\varepsilon$ .

Because  $y$  and  $x$  are observable data vectors, equation (3) can be estimated by maximum likelihood estimation using the restrictions implied in both the coefficient matrix  $\pi$  and the covariance matrix of the error  $\mu$ . Since the reduced form parameters of equation (3) remain unaltered when  $\lambda$  is multiplied by a scalar and  $\gamma$  and  $\sigma_\nu^2$  are divided by the same scalar, the estimation of (1) and (2) requires a normalization of the parameters in (1), and a convenient way to achieve this is to constrain one element of  $\lambda$  to some pre-assigned value.

Since the estimation of  $\lambda$  and  $\gamma$  is obtained by constraining one element of  $\lambda$  to some arbitrary value, it is useful to standardize the regression coefficients  $\hat{\lambda}$  and  $\hat{\gamma}$  as follows:

$$\hat{\lambda}^s = \hat{\lambda} \left( \frac{\hat{\sigma}_{IE}}{\hat{\sigma}_y} \right) \qquad \hat{\gamma}^s = \hat{\gamma} \left( \frac{\hat{\sigma}_x}{\hat{\sigma}_{IE}} \right)$$

The standardized coefficient measures the expected change in the standard-deviation units of the dependent variable due to a one standard-deviation change of the given explanatory variable when the other variables are held constant. Using the estimates of the  $\gamma^s$  vector and setting the error term  $\nu$  to its mean value of zero, the predicted *ordinal* values for the informal economy (*IE*) can be estimated by using equation (2). Then, by using information regarding the specific value of informal activity for some country (if it is a cross country study) or for some point in time (if it is a time series study), obtained from some other source, the within-sample predictions for *IE* can be converted into *absolute* series.

The MIMIC approach is chosen as the most appropriate method to calculate the size of the informal economy for this sample of countries because of the following reasons:

- Tax auditing and other similar survey based methods are unavailable for most Caribbean countries in the sample.
- The methods based on statistical and labor force discrepancies present, as described before, serious limitations and weaknesses.
- Aside from above mentioned critiques, the electricity, transaction and currency demand approaches share a common crucial limitation. Since the three approaches are

based on time series regressions, extra information<sup>12</sup> for *each country* is required in order to pin down the absolute size of the informal economy. Without this extra knowledge, the most one can learn is the growth pattern of the informal economy. While for some countries like Argentina, Mexico and Chile this extra information is possible to obtain, for the ECCU countries and other Caribbean countries there is no such data. On the contrary, the proposed cross section MIMIC approach requires extra information regarding the absolute size of the informal economy for *only one country* in the sample.

This paper only focuses on *real* cause and indicator variables, as opposed to *monetary* ones, which might underestimate and misrepresent the relevance of the informal economy in countries subject to a high degree of dollarization in circulating currency<sup>13</sup>. This occurs because although monetary data is easily obtained for local currency, data is not available for foreign currency circulating. In this sense, the present study follows closely the study conducted by Loayza (1997) who estimates the size of the informal economy for 14 Latin American countries for the early 90s using real variables<sup>14</sup>.

---

<sup>12</sup> This extra information could be obtained either by knowing the absolute value of the informal economy for a certain year or by assuming a base year without informal economy.

<sup>13</sup> There exist the presumption and some concrete evidence based on Feige et al. (2001, 2002) and Feige (2003, 2005) that dollarization in circulating currency is a relevant issue for both low inflation and non crisis countries like the ECCU, because of tourism and currency substitution issues, and for typically high inflation countries like Argentina and Mexico, due to asset substitution issues.

<sup>14</sup> Loayza uses the used tax burden, labor market restrictions and governance measures as cause variables and tax evasion and the share of the labor force contributing to social security schemes as indicators of the informal economy.

### III. DATA

The cross section study considers the ECCU countries and 26 mainly Latin American countries for the early 2000s<sup>15</sup>. The countries included are: Antigua and Barbuda, Argentina, Barbados, Belize, Brazil, Chile, Colombia, Costa Rica, Cyprus, Dominica, Dominican Republic, Ecuador, El Salvador, Fiji, Grenada, Guatemala, Guyana, Honduras, Jamaica, Malta, Mexico, Nicaragua, Panama, Paraguay, Peru, St. Kitts and Nevis, St. Lucia, St. Vincent and the Grenadines, The Bahamas, Trinidad and Tobago, Uruguay and Venezuela. The cause and indicator variables considered, and their expected relationship with the size of the informal economy, are presented below<sup>16</sup>.

#### A. Cause variables

First, the *tax burden* is proxied by the average of corporate and personal marginal income tax rate. The highest rate is used when there is more than one rate. The hypothesis is that an increase of the tax burden boosts the incentive to work in the informal economy.

Second, increases in legal restrictions on the labor market are hypothesized to increase the size of the informal economy. *Labor rigidities* are captured by two alternative indices<sup>17</sup>:

---

<sup>15</sup> Most of the data is based on 2002 or 2003 information.

<sup>16</sup> More details regarding the construction and sources of the data used can be found in the Appendix.

<sup>17</sup> Most empirical studies use the labor rigidity index developed by Forteza and Rama (2001). This index is constructed by averaging the normalized values of four labor-related variables, including minimum wage restrictions, mandated benefits, labor unions (measured by the membership of the labor movement as percentage of the labor force) and government employment (measured as the employment in the government as percentage of the labor force). These last two factors are not included in the labor rigidity indices developed in this study for the following reasons:

*Labor unionization* seems to be, at least for emerging and developing countries, a consequence of the informal economy more than its cause since bigger informal sectors seem to weak the bargain power of the workers in the formal sector. For example, countries with well known important informal sectors, like Peru

- Labor rigidity index #1 considers minimum wage constraints and is calculated as the ratio of the annual minimum wage to GDP per capita.
- Labor rigidity index #2 equals the average of two normalized components, one of which is the minimum wage ratio as described before, and the other of which captures mandated benefits, as measured by the social security contribution rates as a percentage of wages. Following Loayza (1997) in spirit, this second rigidity index is divided by GDP per capita in order to account for differences in labor productivity across countries.

Third, the *importance of agriculture* in the economy is included, since many studies endorse the idea that informal working is highly segmented by sector, with clear prevalence in the agricultural and related sectors. One of the most important reasons for this is the minimum enforcement capacity prevalent in rural areas. The importance of agriculture is measured as agriculture and food exports as a percentage of total exports to reduce problems of endogeneity<sup>18</sup>. The more prominent the agriculture sector, the bigger the expected size of the informal economy.

Fourth, following Giles (1999) the *inflation* rate is included to allow for the upward “creep” of tax brackets, and the associated incentive for tax-payers to engage in informal

---

and Ecuador, have very low degree of unionization, approximately 5 to 10 percent of the labor force; while countries with traditional lower informality like Argentina and Mexico have percentages close to 35 percent. For this reason, labor unionization is included as an indicator variable and it is expected to be negatively related with the size of the informal economy.

Higher *government employment*, far from increasing labor rigidity and consequently incrementing the size of the informal economy, could reduce the informality, since most public employees contribute to social security systems and are regulated by most institutions of the society. This variable is not included separately as another cause variable because it might be also subject to the Wagner’s law and consequently subject to some endogeneity problem if the degree of development is related with the size of the informal economy.

<sup>18</sup> The share of agriculture as percentage of GDP was also considered with similar results.

activities. A more pervasive effect of inflation is that, as it tends to be uneven across sectors, it alters the income distribution, and this may induce disrespect for tax law. The higher the inflation, the larger the expected size of the informal economy.

Last, the *strength of enforcement system* is proxied by an average of three indicators developed by International Country Risk Guide (ICRG), specifically quality of bureaucracy, corruption in government and rule of law. The stronger the enforcement capability of government, the lower is the expected size of the informal economy.

## **B. Indicator variables**

First, following Loayza (1997) the percentage of the labor force *contributing to the social security system* is included. The bigger the informal economy, the lower the expected number of contributors to the social security system.

Second, the *degree of unionization*, measured as the percentage of labor force with membership in some labor union, is considered. The bigger the informal economy, the weaker the bargain power of the workers in the formal sector and, therefore, the lower the degree of unionization.

Last, the *gross enrollment ratio for secondary school* is included as an informal economy indicator. Most countries in the world have signed the International Labor Organization Convention 138, which made fourteen the minimum working age; however one of the most well-recognized consequences of the informal economy is child labor and the effect

it has on rates of education enrollment<sup>19</sup>. Thus, the bigger the informal economy, the lower is the expected enrollment rate.

#### **IV. EMPIRICAL RESULTS**

##### **A. Preliminary Evidence**

Table 2 shows the correlation between each cause and indicator variable. If both the conjectured relation between the cause variables and the informal economy and the hypothesized association between the informal economy and its indicators are present, there should be a specific pattern in the correlations between the cause and indicator variables. For example, if stronger labor rigidities are expected to increase the size of the informal economy and the latter effect is supposed to decrease the percentage of contributors to social security, then there should exist a negative relationship between labor rigidity and percentage of contributors to social security. It is clear from Table 2 that, aside for the relationship between tax burden and degree of unionizations (top-right cell), all the rest of the observed correlations matches their expected signs. Therefore, there seems to be strong preliminary support for our hypothesis.

TABLE 2 HERE

---

<sup>19</sup> The primary net enrolment rate would be maybe the best proxy to capture this phenomenon, however because of data unavailability for most ECCU countries and since for the countries with such information there is a high correlation with the secondary gross enrolment rate, the last measure is used.

## B. MIMIC Estimation Results

The benchmark MIMIC specification, Model 1, is represented in Figure 1. The labor rigidity index #1, the tax burden, importance of agriculture and inflation are the cause variables of the informal economy, while the number of contributors to the social security system, the degree of unionization and the gross enrollment ratio for secondary school are the indicator variables<sup>20</sup>. Before analyzing the estimation results it is important to remark that several goodness-of-fit statistics support the underlying model (see grey box in Figure 1). These set of goodness-of-fit measures are based on fitting the model to sample moments, which means to compare the observed covariance matrix to the one estimated on the assumption that the model being tested is true. The Discrepancy function (CMIN) is one of the most common fit tests and it is the minimum value of the discrepancy function between the sample covariance matrix and the estimated covariance matrix. The chi-square value should not be significant if there is a good model fit, while a significant chi-square indicates lack of satisfactory model fit. The goodness-of-fit index (GFI) and the adjusted goodness to fit index (AGFI) tests are also measures of discrepancy between the predicted and observed covariances. The GFI can be interpreted as the percent of observed covariances explained by the covariances implied by the model. The AGFI is a variant of the GFI which adjusts GFI for degrees of freedom. By convention, both GFI and AGFI should be equal to or greater than 0.90 to accept the model. The root mean square error of approximation (RMSEA) is also a fit test that some authors argue is less

---

<sup>20</sup> Although most variables are subject to certain extent to some endogeneity problem, strength of enforcement system might be the one which could be more severely affected. For this reason it is not included in the benchmark specification.

sensitive to sample size than the above mentioned tests (see for example Fan et al. (1999)). By convention, there is good model fit if the RMSEA less than or equal to 0.05.

The coefficients on the causal and indicator variables have the expected signs and are statistically significant mostly at 1 or 5 percent. Specifically, one standard deviation increases in the tax burden, labor rigidities, importance of agriculture and inflation increase the size of the informal economy by 0.274, 0.519, 0.404 and 0.465 standard deviations, respectively. Even more, the joint influence of these four cause variables explains approximately 79 percent of the variance of the informal economy.

We find that increases in the informal economy reduce the number of workers contributing to the social security system, the degree of unionization and the secondary enrollment ratio, and explains 76, 35 and 57 percent of their respective variances.

FIGURE 1 HERE

Alternative MIMIC specifications are considered for robustness purposes. Models 2 and 3, respectively displayed in Figures 2 and 3, include an alternative measure of labor rigidity and strength of enforcement system. They both confirm the results obtained in the benchmark model, and Model 3 also presents evidence suggesting that the strength of enforcement appears to be an important determinant of the size of informal economy.

FIGURE 2 HERE

FIGURE 3 HERE

### C. Estimations of the Size of the Informal Economy

Using the estimates of the benchmark model, Table 3 and Figure 4 show the standardized *ordinal* values of the size of the informal economy for the countries in the sample. Since these ordinal values only identify the relative position of the countries, we set the informal economy of Jamaica equal to 35 percent of total GDP in order to estimate the *absolute* values of the informal economy as percentage of total GDP<sup>21</sup>. Bahamas, Cyprus, Grenada, St. Kitts and Nevis, Trinidad and Tobago and Barbados are among the countries with the smallest informal economies, with values ranging from 16 to 25 percent of GDP. These values are among the lowest not only for the Caribbean region, but also in relation with most Latin American countries. On the other hand, St. Vincent and the Grenadines, Belize and Dominican Republic are among the countries with the largest informal economies in the Caribbean, with sizes varying between 41 and 51 percent. Notwithstanding, these estimates are smaller than those for the countries with the highest levels of informal activity in Latin America like Paraguay and Nicaragua, with values around 70 percent. The rest of the Caribbean countries have sizes of the informal economy similar to the most developed countries in Latin America like Argentina, Chile, Mexico and Uruguay.

As detailed before, the *absolute* values of the informal economy, unlike the *ordinal* measures, rely on extra information pinning down the absolute value of the informal economy for one country, in this case Jamaica. The information for Jamaica is based on a comprehensive study by De La Roca et al. (2002) that used different methodologies and

---

<sup>21</sup> According to a study conducted by De La Roca et al. (2002), the informal economy in Jamaica accounted for about 35 percent of the total GDP in 2000-2001.

data collected as part of the 2001 Jamaica Survey of Living Conditions, and is therefore a very attractive data source to pin down the absolute series of the informal economy<sup>22</sup>. Since the *order* of countries according to the size of the informal economy is independent of this extra information, while the *absolute* values of the informal economy do depend on this data, a word of caution should be taken regarding the use of the latter values as accurate measures of the degree of informality.

TABLE 3 HERE

FIGURE 4 HERE

Table 4 shows the absolute values of the informal economy for the ECCU and other Caribbean countries by using the different specifications employed in Model 1, 2 and 3. It can be inferred that the estimated absolute sizes of the informal economy are similar across models. The Spearman's rank correlation coefficient is 0.89 between Model 1 and 2, 0.98 between Model 1 and 3 and 0.85 between Model 2 and 3. The null hypothesis that the estimated absolute sizes of the informal economy are independent across models is rejected at the 1 percent level of significance for all comparisons.

TABLE 4 HERE

---

<sup>22</sup> De La Roca et al. (2002) studies the informal economy for Jamaica in the early 2000s to evaluate the impact of the 1990's structural reforms. They found similar informal economy estimates using macroeconomic approaches like monetary and electricity consumption approach and microeconomic approaches based on the addition of the total amount of wages of the informal workers, the unreported income of the formal workers in the economy and the value added generated by household's independent activities whether agricultural or non-agricultural.

The estimates reported here are similar to those for “late 90s” reported in Schneider (2002). For 15 common countries, there is a positive correlation of 0.37 between the absolute sizes of the informal economy, and the spearman’s rank correlation test has a rho value of 0.44, which rejects at the 10 percent level of significance the null that these rankings have zero correlation.

#### **D. Relative Contribution of Each Cause Variable to the Size of the Informal Economy**

Table 5 shows the relative contribution of each cause variable to the size of the informal economy for all countries studied, and Figure 5 displays these values for the Caribbean economies. On average tax burden, labor rigidity, importance of agriculture and inflation constitute around 35, 26, 31 and 8 percent of the overall size of the informal economy respectively. However, this profile differs importantly across countries:

- For countries like Antigua and Barbuda, Barbados and Trinidad and Tobago the main component influencing the informal economy is the tax burden. For example, for the period under consideration, Antigua and Barbuda has maximum marginal corporate and personal tax rates of 55 and 35 percent respectively.
- For others like St. Vincent and the Grenadines, St. Lucia and Belize the importance of the agriculture sector seems to be one of the most relevant factors, with approximately 75 percent of exports concentrated in agriculture and food products.

- For countries like Paraguay and Dominican Republic the significance of labor rigidities appears to be decisive, with minimum wages representing 170 percent and 90 percent of the corresponding GDP per capita.
- For most of the economies, inflation does not seem to be an important factor determining the size of the informal economy, because of the price stability observed in the second part of the 90s.

## **V. CONCLUDING REMARKS**

This paper estimates the size of the informal economy and the relative contribution of each underlying factor in the ECCU countries and 26 mainly Latin American countries in the early 2000s, being the first study to address this issue for the ECCU economies and many other Central American and Caribbean countries.

Using a structural equation model approach that considers the informal economy as a latent variable with several causes and effects, we find that a stringent tax system and regulatory environment, higher inflation and dominance of the agriculture sector are the key factors in determining the informal economy, representing altogether around 79 percent of the informal economy variance. The results also confirm that a higher degree of informality reduces labor unionization, the number of contributors to social security schemes and enrollment rates in education.

The size of the informal economy differs considerably among countries. While in countries like Paraguay and Nicaragua the informal sector reaches values around 70

percent of total GDP, in economies like Bahamas, Cyprus, Grenada, St. Kitts and Nevis, Trinidad and Tobago and Barbados the informal share has values below 25 percent. The average size of the informal economy for the ECCU and Caribbean countries is around 33 percent of GDP, while for Latin America the average share is 43 percent. Not only do many Caribbean economies have smaller levels of informality than the Latin American countries with the smallest informal economies, but also the Caribbean economies with the most informality have smaller informal economies than the Latin American countries with the biggest informal sector.

We also find that the relative contribution of each cause variable to the informal economy varies significantly across countries. For countries like Antigua and Barbuda and Trinidad and Tobago the most important factor influencing the informal economy is the tax burden. For others like St. Vincent and the Grenadines, St. Lucia and Belize the relevance of the agriculture sector appears to be one of the most important elements, while for economies like Paraguay and Dominican Republic the significance of labor rigidities seems to be crucial.

The above analysis has important policy implications for authorities striving to reduce the degree of informality. For instance, in countries where the informal economy is related to a high tax burden, policy options include lowering and homogenizing effective tax rates across all sectors in the economy. In economies where labor market rigidities generate the informal economy, steps need to be taken to increase labor market flexibility. In countries where inflation is the key factor, priority should be given to tightening monetary policy and stabilizing prices, while in economies with important an agricultural sector, measures to improve the strength and expertise of government officials should be emphasized.

## APPENDIX

### I. DATA CONSTRUCTION AND SOURCES

#### *Causal Variables:*

1. Tax burden: The proxy for tax pressure is the average of corporate and personal marginal income tax rate. The highest rate is used when there is more than one rate. This proxy measure is normalized between 0 and 100. The data correspond mostly for 2003 and is obtained from World Development Indicators 2006 and Bain and dos Santos (2004).
2. Labor rigidity indices: Two alternative measures of labor rigidity are constructed.
  - labor rigidity index #1 is represented by the ratio of minimum wage and GDP per capita normalized between 0 and 100. The minimum wage corresponds to the most general minimum wage regime. When minimum wages vary across sectors, the one for manufacturing (or for commerce, if manufacturing is not available) is reported. When minimum wages vary across regions, the value reported is either a simple average across regions or the minimum wage applicable in the main urban centers. A zero indicates that the country has no government set minimum wage, although minimum wages negotiated at the sectoral level may exist.
  - Labor rigidity index #2 is the normalized average of two components divided by real GDP per capita. The first component captures minimum wages restrictions and corresponds to labor rigidity index #1, while the second element represents mandated benefits and it is measured by the contribution rates (as percentage of salaries) for all social security programs for both the employee and the employer. Only for Belize, where the contributions are flat-rate according to earning classes, the normalized legal number of days of maternity leave with full pay without complications is used. Following Loayza (1997) the normalized average of these components is divided by real GDP per capita in order to account for differences in labor productivity across countries.

The data for minimum wages correspond to 2002 and it is mainly obtained from the “Country Reports on Human Rights Practices” (2002). The Country Reports on Human Rights Practices are submitted annually by the U.S. Department of State to the U.S. Congress. The reports cover internationally recognized individual, civil, political, and worker rights, as set forth in the Universal Declaration of Human Rights. For Costa Rica and Mexico information from the respective ministries of labor is used. The social security contribution data correspond mostly to year 2003 and it is obtained from “Social Security Programs Throughout the World”. Maternity leave information correspond to the average of the period 1999-2002 and it is obtained from several online publications from The Clearinghouse on International Developments in Child, Youth and Family Policies, Columbia University.

3. Importance of agriculture: It is measured by the agricultural raw material and food exports (as percentage of total exports) using World Development Indicators 2006 and correspond mainly for 2000. For Dominican Republic the year 2001 and for Fiji the year 2002 information is used.

4. Inflation: Annual average consumer prices inflation for the period 1995-1999. Aside for Antigua and Barbuda in which IMF data is used, the rest of the information is obtained from World Development Indicators 2006.

5. Strength of enforcement system: Following Loayza (1997) the strength of enforcement system is proxied by an average of three subjective indicators reported in the International Country Risk Guide (ICRG) for 2002. The three variables considered are quality of bureaucracy, corruption in government and rule of law. Quality of bureaucracy scores high under “autonomy from political pressure” and “strength and expertise to govern without drastic changes in policy or interruption in government services”. Low scores in corruption in government indicate “high government officials are likely to demand special payments” and “illegal payments are generally expected throughout lower levels of government”. The variable rule of law “reflects the degree to which the citizens of a country are willing to accept the established institutions to make and implement laws and adjudicate disputes”. Higher values are associated with “sound political institutions, a strong court system, and provisions for an orderly succession of power”. ICRG is a publication of Political Risk Services of Syracuse, NY.

### ***Indicators:***

1. Workers contributing to social security: Active contributors to old-age pension schemes, in percent of the labor force. It is based on social security agencies, household surveys and IMF country desks information predominantly for 2002.

2. Degree of unionization: Total union membership considering both public and the private sectors, in percent of the labor force. The data is mainly from “Country Reports on Human Rights Practices” (2002), but also country authority’s information is used.

3. Gross enrolment ratio for secondary school: Total secondary enrolment as a percentage of the corresponding official school-age population, mostly for 2001. The sources of information are Human Development Report 2005 and “Organization of the Eastern Caribbean States. Towards a New Agenda for Growth” (2005).
